Stochastic

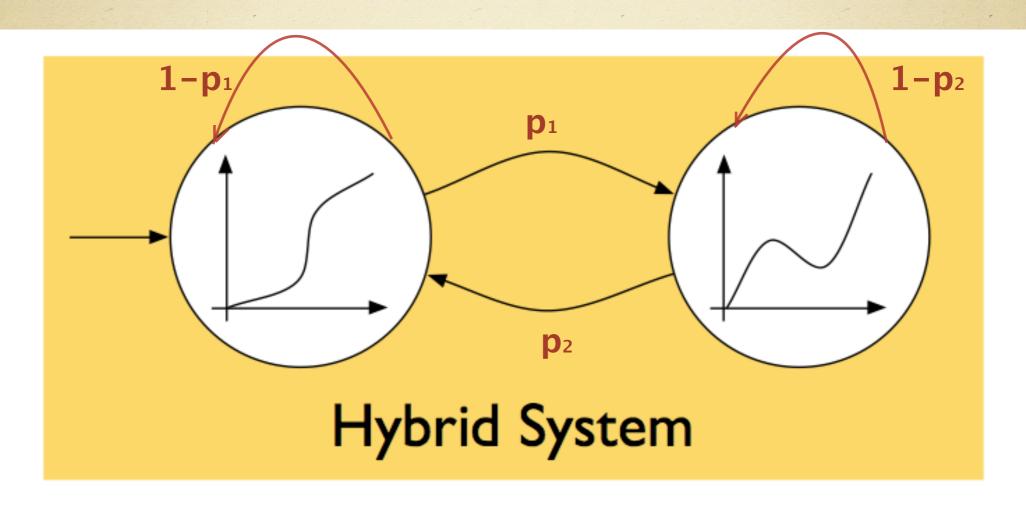

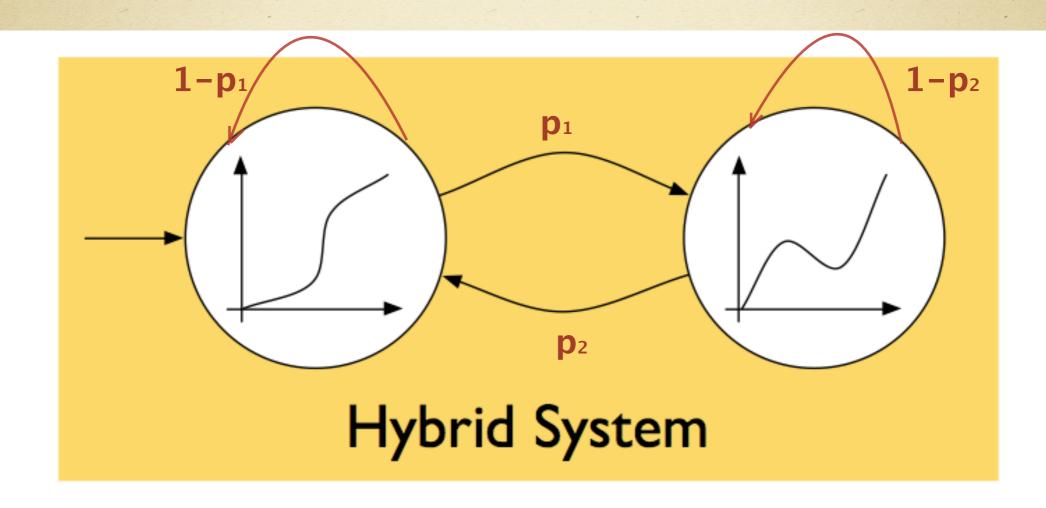

Discrete Control + Continuous Dynamics

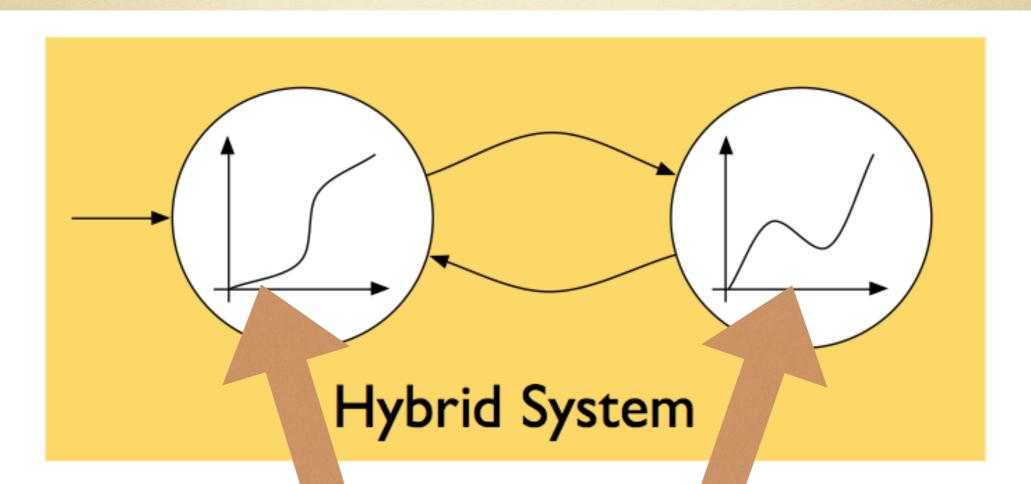

Hybrid System with Parametric Uncertainty

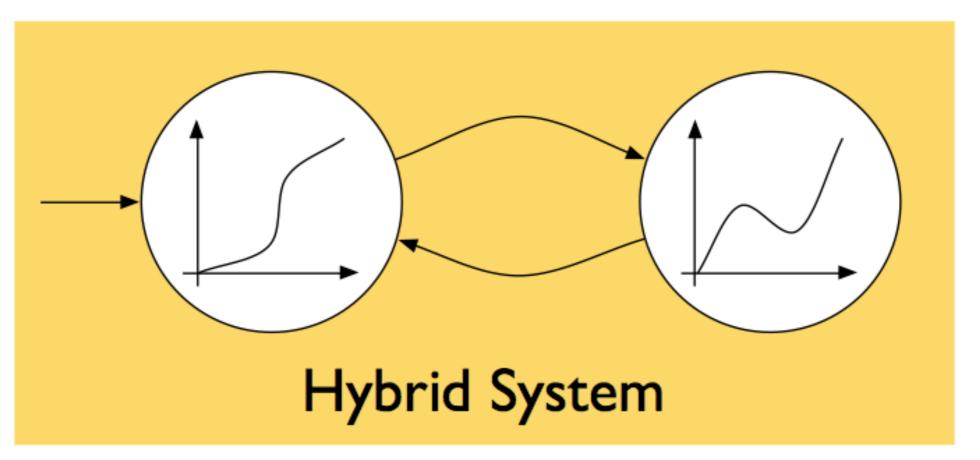

p₁ and p₂ are discrete random variables: Probabilistic Hybrid Automata

When continuous distributions are also allowed:
Stochastic Hybrid Automata

$$dX_t = \mu(X_t, t) dt + \sigma(X_t, t) dB_t,$$

When all above modifications have been applied: General Stochastic Hybrid Automata

SReach considers ...

Definition 1 (HA_p). A hybrid automaton with parametric uncertainty is a tuple $H_p = \langle (Q, E), V, RV, \text{ Init, Flow, Inv, Jump, } \Sigma \rangle$, where

- The vertices $Q = \{q_1, \dots, q_m\}$ is a finite set of discrete modes, and edges in E are control switches.
- $-V = \{v_1, \dots, v_n\}$ denotes a finite set of real-valued system variables. We write V to represent the first derivatives of variables during the continuous change, and write V' to denote values of variables at the conclusion of the discrete change.
- $-RV = \{w_1, \dots, w_k\}$ is a finite set of independent random variables, where the distribution of w_i is denoted by P_i .
- Init, Flow, and Inv are labeling functions over Q. For each mode $q \in Q$, the initial condition Init(q) and invariant condition Inv(q) are predicates whose free variables are from $V \cup RV$, and the flow condition Flow(q) is a predicate whose free variables are from $V \cup \dot{V} \cup RV$.
- Jump is a transition labeling function that assigns to each transition $e \in E$ a predicate whose free variables are from $V \cup V' \cup RV$.
- Σ is a finite set of events, and an edge labeling function event : $E \to \Sigma$ assigns to each control switch an event.

SReach considers ...

Definition 2 (PHA_r). A probabilistic hybrid automaton with additional randomness H_r consists of Q, E, V, RV, Init, Flow, Inv, Σ as in Definition 1, and Cmds, which is a finite set of probabilistic guarded commands of the form: $g \to p_1 : u_1 + \cdots + p_m : u_m$, where g is a predicate representing a transition guard with free variables from V, p_i is the transition probability for the ith probabilistic choice which can be expressed by an equation involving random variable(s) in RV and the p_i 's satisfy $\sum_{i=1}^m p_i = 1$, and u_i is the corresponding transition updating function for the ith probabilistic choice, whose free variables are from $V \cup V' \cup RV$.

$$x \ge 5 \rightarrow p_1 : (x' = \sin(x)) + (1 - p_1) : (x' = p_x),$$

 $p_1 \sim U(0.2, 0.9), \text{ and } p_x \sim B(0.85)$

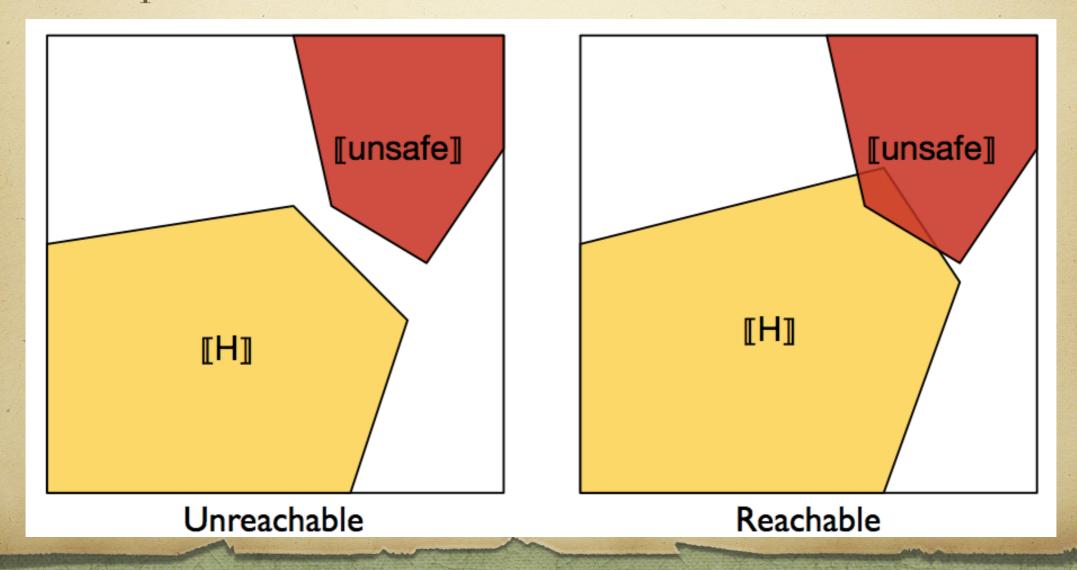

SReach can handle...

Definition 3. The probabilistic bounded k step δ -reachability for a HA_p H_p is to compute the probability that H_p reaches the target region T in k steps. Given the set of independent random variables \mathbf{r} , $Pr(\mathbf{r})$ a probability measure over \mathbf{r} , and Ω the sample space of \mathbf{r} , the reachability probability is $\int_{\Omega} I_T(\mathbf{r}) dPr(\mathbf{r})$, where $I_T(\mathbf{r})$ is the indicator function which is 1 if H_p with \mathbf{r} reaches T in k steps.

Definition 4. For a PHA_r H_r , the probabilistic bounded k step δ -reachability estimated by SReach is the maximal probability that H_r reaches the target region T in k steps: $max_{\sigma \in E} Pr_{H_r,\sigma,T}^k(i)$, where E is the set of possible executions of H starting from the initial state i, and σ is an execution in the set E.

Reachability Analysis of Hybrid Systems

Can a hybrid system H run into a goal region of its state space?

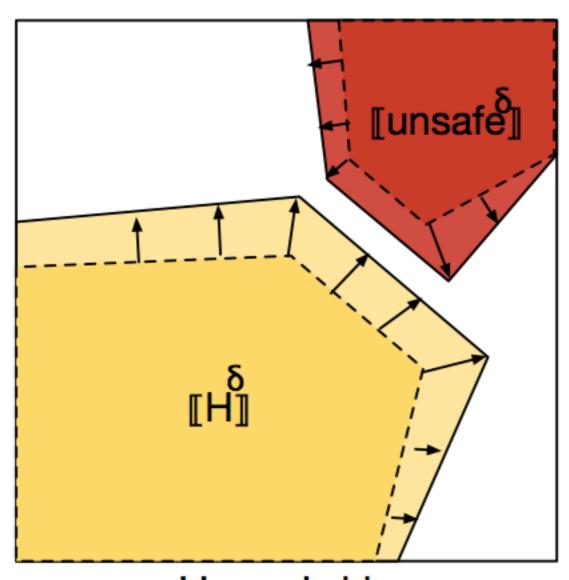

Bounded Reachability Analysis of Hybrid Systems

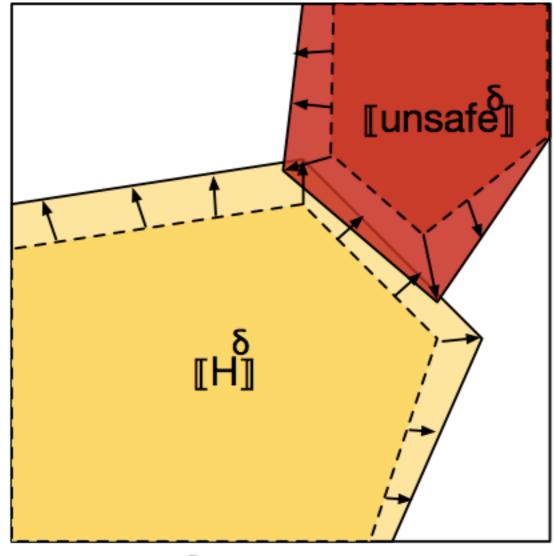

- The standard bounded reachability problems for simple hybrid systems are undecidable.
 - > 1. Give up
 - 2. Don't give Up
 - A. Find a decidable fragment and solve it
 - B. Use approximation

δ-Reachability Analysis of Hybrid Systems

- Solven δ ∈ Q⁺, [H⁰] and [Goal⁰] over-approximate [H] and [Goal] respectively.
- > So, the δ-reachability problem asks

Unreachable

δ-reachable

δ-Reachability Analysis of Hybrid Systems

- > Decidable for a wide range of nonlinear hybrid systems: polynomials, log, exp, trigonometric functions, ODEs ...
- > Reasonable complexity bound (PSPACE-complete)
- > When it says
 - Unreachable the answer is sound
 - δ-Reachable may lead to an infeasible counterexample,
 you may try a smaller δ and possibly get rid of it

SReach's algorithm

Algorithm 1 SReach

```

                                                                     > perform statistical test
21:
22:
        return ST.output
23: end function
```

SReach's algorithm

- 3 δ-complete bounded reachability analysis technique (dReal/dReach) + statistical testing techniques
- advance the reasoning power of SMT-based bounded model checking to probabilistic models
- > the full non-determinism and nonlinear dynamics of models will be considered
- > the coverage of simulation will be increased
- the zero-crossing problem can be avoided
- controllable error bounds on the estimated probabilities

- > SReach can answer two types of questions:
 - (1) Does the model satisfy a given reachability property with probability greater than a certain threshold? hypothesis testing
 - > Hypothesis testing methods: Lai's test, Bayes factor test, Bayes factor test with indifference region, and Sequential probability ratio test.

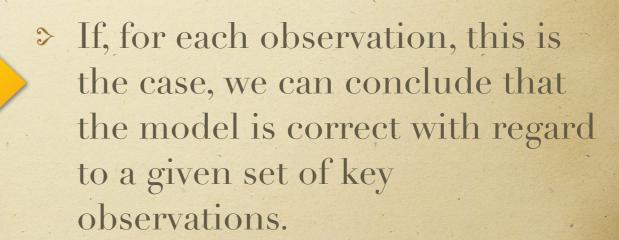

- > SReach can answer two types of questions:
 - > (2) What is the probability that the model satisfies a given reachability property? statistical estimation
 - Statistical estimation methods: Chernoff-Hoeffding bound, Bayesian interval estimation with beta prior, and Direct sampling.

Model Falsification: whether consistent with existing key observations.

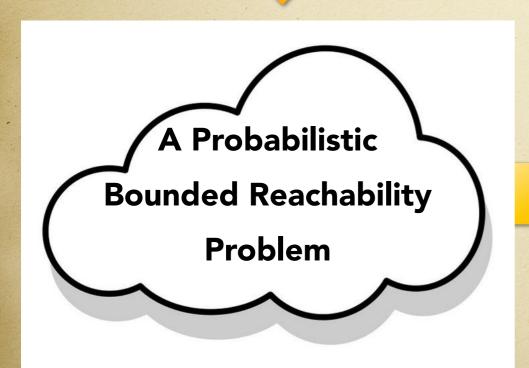

A Probabilistic
Bounded Reachability
Problem

- Expressing each observation as a goal region, will this model reach the goal region in bounded steps with the predefined desirable probability?
 - > If not, the model is incorrect regarding the given observation.

Parameter Synthesis: How to control the system to reach good states with a desirable probability?

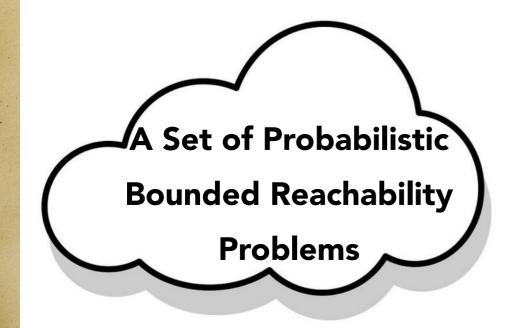

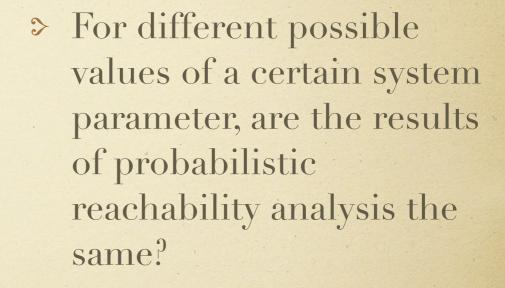

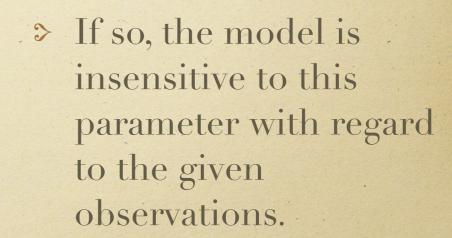

- Does it exist a parameter combination for which the model reaches the given goal region with a desirable probability in bounded steps?
- Considering an assignment of a certain set of system parameters, if a witness is returned, this assignment is potentially a good estimation for those parameters.
 - The goal here is to find an assignment with which all the given goal regions with desirable probabilities can be reached in bounded steps.

Parametric Sensitivity Analysis: Testing the robustness of the model, Understand the relationships between parameters and the model, etc.

Table 5: #Ms = number of modes, K indicates the unfolding steps, #ODEs = number of ODEs in the unfolded formulae, #Vs = number of total variables in the unfolded formulae, #RVs = number of random variables in the model, δ = precision used in dReach.

Future work

- Stochastic Hybrid Systems with stochastic flows: stochastic differential equations
 - > introduce a type of constraints for SDEs,
 - design a theory solver handling this type of constraints: reduction to PDEs, stopping time (moment generating functions), ...
 - > then integrate with dReal solver.

Thanks!
